INTRODUCTION

Milk composition in terms of components considered beneficial to human health can be directly influenced by dairy cattle feed. This applies in particular to certain fatty acids like omega 3 and conjugated linoleic acids (CLA), whose concentration in milk could be increased following the addition of oilseeds to the diet. This study aims to assess the effect of the botanical composition of the herbage and the conservation method on the fatty acid composition of milk.

RESULTS AND DISCUSSION

Influence of the botanical composition of grass, hay or silage on the fatty acid composition of milk

RESULTS AND DISCUSSION

Fatty acid content of fodder

- The fatty acid profile of fresh grass was only slightly influenced by the botanical composition.
- Haymaking led to losses of fatty acids (mainly C18:3 and C18:2) varying between 10% (GR) and 35% (GL).
- Ensiling did not cause an absolute loss of fatty acids but rather a different distribution, i.e. a reduction in C18:3 and an increase in palmitic acid C16:0.

CONCLUSIONS

The botanical composition of the herbage influences the fatty acid composition of milk. Alfalfa in fresh grass proves to be favorable for the presence, in milk, of fatty acids considered to be beneficial to human health, such as omega 3.
